ABSTRACT

- The invention relates to a circuit arrangement for operating at least one light-emitting diode LED in an electrical circuit at a service voltage, which is greater than the forward voltage of the at least one light-emitting diode which is to be operated. In this connection, the light-emitting diode is PWM-controlled.
- The circuit comprises reactances that are connected in series at both connections of the light-emitting diode, an additional switching means between the terminals, and a full-wave rectifier circuit, such that the circuit is protected against short-circuits on the service voltage and on ground while the LED can continue to be triggered.
